Increase in venous [K+] During Hyperbaric Exposure Independent of Changes in pH or O2 Concentration

Increase in venous [K+] During Hyperbaric Exposure

Abstract

Plasma potassium regulation is important for function of numerous cells in the body. Changes in potassium levels during exposure to an increased O2 concentration is thought to be the result of the changes in pH and increasing reactive oxygen species. However, the effects of hyperbaria on plasma potassium concentration are not well understood.

Eight subjects were exposed to 1.3 atmospheres absolute (ATA) of hyperbaric air for 90 minutes, 10-times (M-F) over 12-days. Another eight subjects were exposed to 100% oxygen at 1 ATA over the same interval. Four venous blood draws were taken. On day 1 the first draw was taken immediately preceding treatment and the second was taken immediately following treatment. The third draw was taken prior to the 10th treatment and the 4th draw was taken 72 hours post final treatment. We analyzed samples on a blood gas analyzer and performed statistical analysis using a paired Wilcoxon signed-rank test.

The concentration group saw strong trend towards an increase in the potassium concentration from 4.09 ± 0.12 (mmol/L) to 4.28 ± 0.28 (mmol/L) ($p = 0.065$). In the hyperbaric group we see a significant increase in potassium concentration from 4.19 ± 0.26 (mmol/L) to 4.55 ± 0.27 (mmol/L) ($p = 0.0068$). In the concentration group we also see a significant increase in pH concentration from 7.37 ± 0.03 to 7.39 ± 0.01 ($p= 0.021$). A similar significant increase is not seen in the hyperbaric group.

These finding suggest that changes in potassium concentration in response to hyperbaria are not the result of oxygen concentration nor pH. Possible explanations include increased nitrogen levels due to hyperbaric air, increased CO2 concentration in hyperbaric chamber or changes in the activity of Na+,K+ ATPase pumps at the cellular level which may be a homeostatic response to combat pulmonary edema

Keywords: Potassium, Hyperbarics, Hyperoxia

Introduction

Administering oxygen O_2 has been proven to be an effective treatment for many different ailments. By varying both pressure and inspired O_2 gas concentration, three of the main modes of O_2 administration are obtained which are hyperbaric O_2, concentrated O_2 and hyperbaric treatment. According the UHMS hyperbaric oxygen therapy (HBO2) is defined as exposure to near 100% O_2 while inside a pressurized chamber at greater than sea level pressure.1 As of

July 2021 the FDA has cleared HBO2 for 13 different conditions.2 In contrast hyperbaric treatment is exposure to an increase in pressure without an increase in administer O_2 concentration. Finally concentrated oxygen is the exposure to O_2 gas with a higher concentration of O_2 than normal air. Even though these protocols are relatively similar their effects on the body can vary in some key ways.

Plasma potassium levels are dependent on a multitude of factors and result from the interplay of intercellular and extracellular changes as well as intake and execration rates.[@RN51] Hypoxia has been shown to cause an increase in arterial potassium levels.5 Hypoxia has also been shown to effect Voltage gated K+ channel expression in pulmonary arterial myocytes.6-7 However the effects of Hyperoxia and Hyperbaria on these channels and plasma potassium levels remains unclear.
